ABSTRACT:
Experimental animals and human post-mortem studies concerning renal effects of tramadol addiction showed histopathological changes in proximal tubules. This study investigates early changes in function and structure of proximal tubules to tramadol addiction. The study included 44 males (G₁ = 23 controls, G₂ = 21 tramadol addicts). The measured urinary parameters were: urinary alpha-1-microglobulin (U.α₁-m), urinary leucine aminopeptidase (U.LAP), urinary N-acetyl-β-D-glucosaminidase (U.NAG). Urinary tramadol (U.Tr) was measured in G₂. In G₂, levels of U.α₁-m, U.LAP and U.NAG were increased in comparison with G₁. These changes were insignificant. U.Tr did not show any correlation with any parameter in G₂. Tramadol addiction may affect proximal tubules. This study is a Preliminary assessment for the subclinical renal effects of tramadol.

Key words: Alpha-1-microglobulin, Tramadol, Leucine aminopeptidase, N-acetyl-beta-D-glucosaminidase, Nephrotoxicity.

INTRODUCTION:
In Egypt, drug addiction is considered one of the serious problems that worry both people and the government. It affects young people within their productive years. It may lead to many problems such as social maladaptation, decreased work productivity and job loss (El-Akabawi, 2001).

Tramadol hydrochloride was initially developed in the 1970’s. It was registered in 1977 in Germany, 1994 in the UK, and 1995 in the US (Grond, et al, 2004). Clinical and experimental studies demonstrated that tramadol did not induce tolerance and dependence on repeated administration (Miranda, et al, 1998 and Kitahara, et al, 2009). On the other hand, results of other studies suggest that tramadol may have abuse liability under some conditions or in certain populations (Jjaderborn, et al, 2009 and Lanier, et al, 2010). Post-marketing surveillance studies consistently showed that the abuse and diversion of tramadol was relatively low (Knisel, et al, 2002). However, a significant finding was that for the cases of tramadol abuse, 97% of the drug addicts used tramadol in combination with other drugs or they had a previous history of addiction to substance of abuse (Cicero, et al, 1999), implying that the abuse liability of tramadol might be ignored in poly-drug abuser population (Degenhardt, et al, 2006). Another epidemiological surveys demonstrated that tramadol was very popular in the drug abuse population, which was often used as a substitute for heroin and other opioids, or combined with other drugs to achieve certain desired effects, or to avoid some undesired effects (Li, et al, 2011 and Liu, et al, 2011), indicating that tramadol may have a higher abuse liability when co-abused with other opioids even though the abuse potential of tramadol itself is relatively low.

In humans body, tramadol undergoes extensive and complex metabolism in the liver via cytochrome P450 system, with 23 metabolites identified: 11 phase I identified and 12 phase II conjugates (Wu, et al, 2002). Thirty per cent of the tramadol is excreted through the kidneys unmetabolised, while the remaining is metabolised by O-and N-demethylation, followed by conjugation with glucuronic acid and sulphates (Gutstein, et al, 2001 and Leppert, et al, 2011).

Metabolites of the drugs that are excreted from kidneys may cause cellular damage leading to kidney dysfunction. Various urinary parameters of the kidney such as alpha-1-microglobulin (α₁-m) was proved useful to assess functional integrity of proximal tubules whereas urinary
kidney-specific enzymes such as brush-border leucine-aminopeptidase (LAP) and lysosomal N-acetyl-β-D-glucosaminidase (NAG) are indicators for structural integrity of proximal tubules (Mueller, et al, 1997).

The present work is a preliminary study to investigate the effect of tramadol addiction among Egyptian drug addicts on proximal tubular functional and structural integrity by measuring urinary kidney parameters as indicators of early alterations of the kidney normal function.

SUBJECTS AND METHODS:

A) Subjects:

Male drug addicted participated in the present study were recruited on voluntary bases from those attended the out-patient clinic, Institute of Psychiatry, Ain-Shams University, for treatment of drug addiction. All participants were subjected to interview using a questionnaire designed to obtain information on previous medical and occupational history, medication intake, actual health status, and subjective symptoms. All subjects underwent a routine clinical examination and a routine urinalysis. The interview and clinical examination were performed by the clinic physicians under the supervision of one of the authors. The drug addicts were excluded from the present study if they had:

1. A history of kidney disease or any disease likely to impair renal function or affect the urinary excretion of the investigated parameters (e.g. diabetes mellitus, hypertension, urinary tract disease).
2. A previous or present exposure to agents capable of damaging the kidney (heavy metals such as lead, cadmium and other nephrotoxins such as organic solvents).
3. Regular and prolonged treatment by drugs affecting the kidney (e.g. aminoglycosides).
4. Dental mercury amalgam fillings as it may affect the kidney.

Forty four Males were then included in the study. The tramadol addicts group (G2) was comprised of 21 males (age: 18 - 40 years, mean ± SD: 28.71 ± 6.64, addiction duration: 6 months - 17 years, mean ± SD: 4.41 ± 4.12), Another 23 healthy non-addicted males (G1) (age: 19-38 years, mean ± SD: 25.44 ± 5.25) were recruited from relatives of the addicted participants after applying the same exclusion criteria and clinical examination.

B) Biological Sampling and Methods:

Morning urine sample was suggested as the best sample for detecting early kidney abnormalities (Zuppi, et al, 1995). Spot morning urine sample was collected by each participant who was instructed to void the urine sample directly into 100 ml sterilized plastic container and centrifuged at 4500 rpm for 5 minutes, and then the clear supernatant was distributed in polyethylene vials (1.5 ml capacity). One vial was used on the same day the urine was collected for measuring tramadol using Immunalysis Tramadol EIA kit (Immunalysis Corporation, USA), and the instrument Biolis 24i Premium (Tokyo Boeki Medical System, Japan). According to the manufacturer of the kit, the method has 100% correlation with GC/MS when 200 ng/ml cutoff calibrator is used. The rest of the vials were stored at -20°C without preservatives until analyzed within 2 weeks for the assessment of:

1. Tubular function by measuring urinary alpha-1-microglobulin (U.α1-m) using ELISA method kit (Assaypro, USA).
2. Tubular structural integrity by measuring urinary activities of Leucine-aminopeptidase (U.LAP) using kit from Randox (UK) and N-acetyl-β-D-glucosaminidase (U.NAG) using kit from Diazyme (USA).
3. Urinary creatinine concentration (U.Cr) using kit from Greiner Diagnostic GmbH (Germany).

Spot urine measurements were used because it has been shown that urinary protein/creatinine ratio (Lemann, et al, 1987) and enzyme activity/creatinine (Jung, 1991) in a random urine sample correlate with 24-hour urinary excretion and eliminate variations caused by changing rates of urine output and provide a measure independent of urine concentration.

C) Statistical Analysis:
Data were presented as mean ± SD. Student t-test was used to compare between the means of parametric data, while Mann-Whitney test was used for non-parametric data. Correlation coefficient (r) was calculated to test the association between two quantitative variables. P-values < 0.05 were considered statistically significant. SPSS version 16.0 was used.

RESULTS AND DISCUSSION:

Among G₁, data of the present study (Table 1) showed a positive correlation between age and each of U.LAP (r= 0.492. P= 0.017) and U.α₁-m (r= 0.521, P= 0.011). Also, regarding the age, the present results (Table 2) showed insignificant difference (P > 0.05) between G₁ and G₂. Urinary parameters of function and structure of proximal tubules was increased (Table 2). These changes were statistically insignificant (P > 0.05). Furthermore, U.Tr/U.Cr showed no correlation with any of the measured urinary parameters in G₂ (Table 3).

Results of the present study (Tables 1 and 2) demonstrated that structural and functional integrity of proximal tubules are deteriorated with age, supporting the report that structural and physiological changes in the kidney are associated with aging (Musso, et al, 2011), and that G₁ matched with G₂ to avoid the effect of age on the measured urinary parameters. Substances with the potential to be abused may have direct or indirect effects on physiologic mechanisms that lead to organ system dysfunction and disease. A multitude of renal diseases are associated with drug abuse because of many different substances used with widely varying pharmacologic effects. Such drugs have been associated with several renal syndromes by varied mechanisms (Kimmel, et al, 2001).

Although total protein in urine provides information of severity of proteinuria, it is protein type that renders a more specific picture of protein composition of urine. Data of the present study

Table (1): Correlation Coefficient (r) between age and urinary parameters of G₁:*

r is statistically insignificant as (P < 0.05),
U. Tr/U. Cr (Urinary Tramadol urinary creatinine ratio),
U.α₁-m/U.Cr (Urinary alpha-1-microglobulin urinary creatinine ratio),
U.LAP/U.Cr (Urinary Leucine-aminopeptidase urinary creatinine ratio),
U.NAG/U.Cr (Urinary N-acetyl-β-D-glucosaminidase urinary creatinine ratio),
G2 (Tramadol addicts group).
uptake is via a constitutive reabsorption pathway in the proximal tubule cells (Christensen, et al, 2007). The structural and functional changes to the proximal tubule cells are a key contributing factor to the development of excessive albumin loss in urine (albuminuria). Albumin present in the urine is often the first indicator of glomerular damage (Thrallkill, et al, 2009) and a decline in renal function. Therefore, the effect of longer addiction duration on the function and structure of both the glomeruli and proximal tubules needs further study.

Tramadol Subclinical Nephrotoxicity

دراسة أولية عن تأثير إدمان الترامادول على سلامة وظيفة وتركيب الأنباب الكلوية بين مدمنين مصريين

إبراهيم الصفتي، أميمة الجمل، أحمد شومان، إبراهيم السيد، أماني هارون، هشام صادق، محمد العشماوي.

يظهر النتائج التي تم جمعها من المرضى الذين خضعوا للدراسة عن تأثير إدمان الترامادول على سلامة وظيفة وتركيب الأنباب الكلوية. وتهدف هذه الدراسة إلى دراسة التأثير المبكر لإدمان الترامادول على سلامة وظيفة وتركيب الأنباب الكلوية.

وقد شملت الدراسة 44 فردًا من الذكور تم تقسيمهم كالآتي: المجموعة الضابطة (G1) وتشمل 23 فردًا، المجموعة المدعمة (G2) وتشمل 21 فردًا من مدمني الترامادول.

تم جمع عينات البول من المشاركين لقياس المؤشرات البولية الآلية في كل عينة: عامل _أ_ -1 ميكروليوبولين (U.α.-m) وليوسين أمينوبنتيديز (U.LAP)، إن - أمينوبنتيديز (U.NAG)، جلوتامين أسلي (Gorn). كذلك تم قياس تركيز الترامادول (U.Tr) في عينات (G1).

وقد أظهرت النتائج أن مستوى الترامادول في (G1) أعلى من مثيلاتها في (G2) وأي من المؤشرات البولية في (U.Tr) ولكن الفرق بينهم لم يكن ذو دلالة إحصائية. كذلك أظهرت النتائج عدم وجود ارتباط ذو دلالة إحصائية بين المستوي البولي لـ (U.Tr) وأي من المؤشرات البولية في (G2).

واللذالك فإن إدمان الترامادول قد يؤثر على الأنباب الكلوية. وهذه الدراسة تقييم أولي للتأثير الكلي على الإكلينيكي للترامادول.
